Nasiko AI Agent Hackathon

The Challenge: Build an AI agent in teams of 1 to 5 that solves a meaningful, non-trivial task with clearly defined capabilities and structured inputs and outputs. Your agent should behave like a reliable service — not a single prompt — and integrate correctly with the Nasiko gateway.

Your system must demonstrate three things:

- **Capability Design** — Well-structured input-output behavior with consistency across different request types
- **A2A Request Compliance** — Strict adherence to the Nasiko gateway request model; responses must be well-formatted and predictable
- **Code Quality & Reliability** — Clean, modular code with proper error handling and graceful edge-case management

What to Build?

Example Use Cases (choose one or bring your own)

- Code analysis or review
- Document processing or summarization
- Query classification or rewriting
- Decision support

Technical Deliverables — all four required:

- Agent Source Code — clean, modular, production-ready
- AgentCard.json — agent registration metadata for the Nasiko registry
- Sample A2A Requests & Responses — demonstrating gateway compliance
- README — setup instructions with a one-command run

Judging criterion

Submissions are evaluated across four dimensions:

- **Problem Value** — Does it solve a real, non-trivial task with a clearly scoped purpose?
- **Gateway Compliance** — Does it strictly follow the A2A request/response format?
- **Code Reliability** — Is it modular, error-handled, and consistent across varied inputs?
- **Output Predictability** — Does the agent behave the same way given the same inputs?
